

Precipitation forecast November-December 2016

Precipitation forecast for the season November to December 2016 has been prepared by applying techniques of statistical downscaling of the output of General Circulation Model (BCC-CSM1.1). Normal to below than normal rainfall is most likely in most parts of the country with maximum negative anomaly in the north-eastern parts. Arrival of fewer western disturbances can be inferred from this situation and therefore less than average rainfall is most likely throughout the country during the season (Nov-Dec, 2016).
